A Decomposition for Invariant Tests of Uniformity on the Sphere

Jean-Renaud Pycke

Abstract. We introduce a $U-$statistic on which can be based a test for uniformity on the sphere. It is a simple function of the geometric mean of distances between points of the sample and consistent against all alternatives. We show that this type of $U-$statistics, whose kernel is invariant by isometries, can be separated into a set of statistics whose limiting random variables are independent. This decomposition is obtained via the so-called canonical decomposition of a group representation. The distribution of the limiting random variables of the components under the null hypothesis is given. We propose an interpretation of Watson type identities between quadratic functionals of Gaussian processes in the light of this decomposition.

1. Introduction

There are various problems in the field of directional statistics where the observations are directions in three dimensions. The surface of a unit sphere may then be used as the sample space for directions in space, each measurement being thought of as a point on a sphere of unit radius. One of the most important hypotheses about a distribution on a sphere is that of uniformity. We introduce in Theorem 2.1 a new $U-$statistic appropriate for testing uniformity on the sphere. A general survey and references concerning tests of uniformity for spherical data are given in [8], chapter 9-10.

The algebraic, geometrical, topological structures of the sphere give rise to particular problems that necessitate the use of special tools. For example the uniform distribution on the sphere does not have an extrinsic mean and therefore the theory of distributions with extrinsic mean (see [1] and [2]) though generic, cannot be applied. In the delicate area of spherical data that do not necessarily have a mean, the invariance under the action of a group can therefore play an important role. The uniform distribution is characterized by its invariance by $O(3)$, the group of isometries of the sphere. Several of the important theoretical distributions occurring in directional statistics are also characterized by invariance under the action of a group. Distributions with rotational symmetry are invariant by the group $SO(2)$ of rotations around a given direction. See [8] p.179 for examples and references about

Key words and phrases. Goodness of fit test, $U-$statistics, group representations.

1
models with rotational symmetry, particularly the celebrated von Mises-Fisher distribution. When the observations are not directions but axes the sample space is the set of couples of antipodal points of the sphere. Axial distributions correspond to spherical distributions invariant by antipodal symmetry. Different distributions (as those of Watson, Bingham) and tests of uniformity or rotational symmetry for axial distributions are discussed in [8]§ 9.4 and 10.7. We provide an example of utilization of group theory in section 3. Theorem 3.1 gives a method for deriving the decomposition of $U-$statistics whose kernel $\Phi$ is $G-$invariant with respect to a compact subgroup $G \subseteq O(3)$, i.e.

(1.1) \[ \forall g \in G : \Phi(g \cdot \xi_1, g \cdot \xi_2) = \Phi(\xi_1, \xi_2). \]

The interest of breaking-down a statistic into a set of uncorrelated components, each measuring some distinctive aspects of the data, has been exemplified in the basic papers [3], [4]. We show in section 4 how the statistic $U_{T,n}$ introduced in Theorem 2.1 can be decomposed in order to build goodness of fit tests whose hypotheses, given by (4.2) are related to invariance under the action of a group. The consistency of these components under certain alternatives is stated in Proposition 4.1 and Proposition 4.2. Example 4.1 deals with the case of rotational symmetry, Example 4.2 with antipodal symmetry. Example 4.3 illustrates the use of the character table of a finite group.

Our decomposition is obtained by combining two different tools, from spectral and group theory respectively. We first use classical spectral methods in order to obtain the well-known decompositions (3.3)–(3.5). In the case where (1.1) holds we obtain a refinement of these decomposition by means of the canonical decomposition (following Serre’s terminology in [15] §2.7) of the linear representations of $G$ given by (3.7).

Interestingly, Watson’s identity and bivariate generalizations introduced in [9] can be interpreted in the light of this approach, see Remark 4.4. Consequently, it seems to provide an efficient tool for deriving quadratic functionals of Gaussian processes arising as the limits in distribution of invariant $U-$statistics.

As it is underlined in the recent paper [6], the problem of finding systematical methods for building goodness of fit tests on the sphere and other manifolds remains widely opened. Giné established in [5] a general framework for testing uniformity on a wide family of sample spaces including the sphere. The eigenfunctions and eigenspaces of the Laplacian play a central role in this framework. Interestingly, the new test of uniformity introduced Theorem 2.1 is also closely related to the Laplacian, more precisely to the zero-mean Green’s function of this operator given by (2.1). Natural extensions of this method to other manifolds and distribution will be discussed in a forthcoming paper.

Throughout this paper $C_l(k), \ (k, \ell \geq 1)$ will denote a sequence of independent random variables such that hold the equalities in law $C_l(k) = \chi^2(\ell) - \mathbb{E}\chi^2(\ell) = \chi^2(\ell) - \ell,$ where $\chi^2(\ell)$ is a chi squared random variable having $\ell$ degrees of freedom.

2. A test of uniformity based on the geometric mean of spacings

Let $S^2 = \{(x, y, z) \in \mathbb{R}^3 : x^2 + y^2 + z^2 = 1\}$ be the unit sphere of the Euclidean space $E_3$. A point $\xi \in S^2$ is specified by spherical coordinates

\[
(\text{colatitude, longitude}) = (\theta, \phi) \in [0, \pi] \times [0, 2\pi]
\]
which are related to the Cartesian coordinates given by \( x = \sin \theta \sin \phi, \ y = \sin \theta \cos \phi, \) and \( z = \cos \theta. \) We consider a population specified by a probability density function \( f(\xi) = f(\theta, \phi) \) with respect to the surface element
\[
d\xi = \sin \theta d\theta d\phi.
\]

Suppose that we wish to test the null hypothesis
\[
H_0 : \xi_i(\theta_i, \phi_i), \ 1 \leq i \leq n, \text{ is a sample of } n \text{ independent observations from the uniform distribution } f(\xi) = f_0(\xi) := 1/(4\pi);
\]
against the alternative hypothesis \( H_1 : f \neq f_0. \) Consider the kernel
\[
(2.1) \quad \Gamma(\xi_1, \xi_2) := -\frac{1}{4\pi} \log \frac{e}{2} (1 - \frac{\xi_1 \cdot \xi_2}{e}) \quad (\xi_1, \xi_2 \in S^2, \xi_1 \neq \xi_2)
\]
where for each \( \xi \in S^2, \xi \) denotes the unit vector emanating from the origin of the Cartesian system. The idea underlying the use of \( \Gamma \) for testing uniformity on \( S^2 \) arises naturally from the interpretation of the celebrated Watson’s statistic
\[
2 \xi(2.3)
\]
and the second equality in (2.1) is readily checked. For the following basic facts about spherical harmonics see, e.g., [13], chapter III. Let \( P_\ell \) and \( P^m_\ell \) denote the Legendre polynomials and associated Legendre functions defined, for \( \ell = 0, 1, ..., \) by
\[
P_\ell(x) := \frac{1}{\ell!2^\ell} \frac{d^\ell}{dx^\ell} (x^2 - 1)^\ell, \quad P^m_\ell(x) := (1 - x^2)^{\ell/2} \frac{d^m P_\ell(x)}{dx^m} \quad (1 \leq m \leq \ell),
\]
(see [13], formulas (7) p.174 and (1) p.246). An orthonormal basis of the Hilbert space \( L^2(S^2) \) equipped with the inner product (3.1) is provided by the set of spherical harmonics \( u^m_\ell \) with (see [13], (II') - (IV') p.262-264)
\[
(2.4) \quad f_\ell^0(\xi) := [(2\ell + 1)/(4\pi)]^{1/2} P_\ell(\cos \theta) \quad (\ell \geq 0)
\]
\[
(2.5) \quad f^m_\ell(\xi) := \alpha^m_\ell \cos(m\phi) P^m_\ell(\cos \theta) \quad (1 \leq m \leq \ell)
\]
\[
(2.6) \quad f^m_\ell(\xi) := \alpha^m_\ell \sin(m\phi) P^m_\ell(\cos \theta) \quad (-\ell \leq m \leq -1)
\]
with \( \alpha^m_\ell = \alpha^{-m}_\ell = [(2\ell + 1)(\ell - m)!/(2\pi(\ell + m)!)]^{1/2} \) for \( m > 0 \). From formula (105) p.311 in [11] we derive the pointwise convergent expansion

\[
(2.7) \quad \log 2 - 1 - \log \left(1 - \frac{\xi_1 \cdot \xi_2}{\ell(\ell + 1)}\right) = \sum_{\ell=1}^{\infty} \frac{(2\ell + 1)P_\ell(\xi_1 \cdot \xi_2)}{\ell(\ell + 1)} (\xi_1, \xi_2 \in S^2; \xi_1 \neq \xi_2).
\]

On dividing both sides of (2.7) by \( 1/(4\pi) \) and in view of (2.1) and (2.4) it becomes

\[
(2.8) \quad \Gamma(\xi_1, \xi_2) = \sum_{\ell=1}^{\infty} \frac{(2\ell + 1)/(4\pi)^{1/2} f_\ell^0(\xi_1 \cdot \xi_2)}{\ell(\ell + 1)} (\xi_1, \xi_2 \in S^2; \xi_1 \neq \xi_2).
\]

In spherical coordinates \( \xi_1 \cdot \xi_2 = \cos \theta_1 \cos \theta_2 + \sin \theta_1 \sin \theta_2 \cos(\phi_1 - \phi_2) \) and the addition formula for Legendre polynomials (see (2.10) \( \Gamma(\xi) \)) may be written

\[
(2.9) \quad [(2\ell + 1)/(4\pi)]^{1/2} f_\ell^0(\xi_1 \cdot \xi_2) = \sum_{-\ell \leq m \leq \ell} f_m^0(\xi_1)f_m^0(\xi_2).
\]

Furthermore, from [12], inequality (35) p.87 involving Legendre functions, we infer that there exists \( a > 0 \) such that \( |f_m^0(\xi_1)f_m^0(\xi_2)| \leq a\ell^{1/2} \) if (\( \theta_1, \theta_2, m, \ell \) \( \neq (0,0,0,0) \). Consequently the general term of the series on the right-hand side of (2.10) is of order \( a/\sqrt{\ell} \), hence converges to 0. When combined with (2.8) and (2.9) this fact ensures the pointwise convergence in the expansion

\[
(2.10) \quad \Gamma(\xi_1, \xi_2) = \sum_{\ell=1}^{\infty} \sum_{-\ell \leq m \leq \ell} \frac{f_m^0(\xi_1)f_m^0(\xi_2)}{\ell(\ell + 1)} (\xi_1, \xi_2 \in S^2; \xi_1 \neq \xi_2).
\]

The convergence is also valid in \( L^2(S^2 \times S^2) \) and the convergence in law of \( U_{\Gamma,n} \) toward the random variable (2.3) is a consequence of Theorem 4.3.1 p.138 in [7]. \( \square \)

3. Decomposition of \( G \)-invariant \( U \)-statistics

For basic definitions and facts about groups and their representations the reader is referred to [15], Part I. Let \( G \) denote the set of compact subgroups of \( O(3) \). These groups (as the cyclic and dihedral groups or the symmetry groups of Platonic solids) are of particular interest in mathematical physics. Some of them are discussed in [15] \( \S 5.1 - 5.6 \). Let \( G \in G \). An isometry \( g \in G \) maps a point \( \xi \in S^2 \) onto \( g\xi \in S^2 \). An action of \( G \) on functions \( f \) and \( \Phi \) defined on \( S^2 \) and \( S^2 \times S^2 \) respectively is given by the shift operators

\[
g \cdot f(\xi) := f(g^{-1}\xi), \quad g \cdot \Phi(\xi, \eta) := \Phi(g^{-1}\xi, g^{-1}\eta), \quad g \in G.
\]

A function \( f \) (resp. a set of functions \( \mathcal{F} \)) is said to be \( G \)-invariant if for each \( g \in G \), one has \( g \cdot f = f \) (resp. \( g \cdot f \in \mathcal{F} \) for each \( f \in \mathcal{F} \)).

Consider the Hilbert space \( L^2(S^2) \) of square integrable functions \( f : S^2 \rightarrow \mathbb{R} \) equipped with the usual inner product and the corresponding norm

\[
(3.1) \quad (f_1, f_2) := \int_{S^2} f_1(\xi)f_2(\xi)d\xi, \quad ||f|| := (f, f)^{1/2}.
\]

Consider a \( U \)-statistic defined as

\[
(3.2) \quad U_n(\xi_1, \ldots, \xi_n) = \frac{2}{(n-1)} \sum_{1 \leq i < j \leq n} \Phi(\xi_i, \xi_j)
\]

where \( \Phi \) is a real valued kernel satisfying the four following conditions.

- C1: \( \Phi(\xi_1, \xi_2) = \Phi(\xi_2, \xi_1) \) and \( \sup_{\xi_i \in S^2} \int_{S^2} \Phi(\xi_1, \xi_2)^2d\xi_2 < \infty \);
where for the second and third equalities we used the pairwise distinct non-null eigenvalues which satisfy
\[ \sum E_\ell \geq 1 \]
respectively. For (b), C1 follows readily from the fact that for each \( \ell \) let
\[ \Phi(\xi_1, \xi_2) = \sum_{\ell=1}^{\infty} \lambda_\ell \sum_{m=1}^{\dim E_\ell} \phi_\ell^m(\xi_1) \phi_\ell^m(\xi_2) \]
(see (2) p.196 in [14] or (4.2.6) p.138 in [7]), can be rewritten in the canonical form (independent of the choice of orthonormal bases in the spaces \( E_\ell, \ell \geq 1 \))
\[ \Phi(\xi_1, \xi_2) \overset{L^2(S^2)}{=} \sum_{\ell=1}^{\infty} \lambda_\ell \Phi_\ell(\xi_1, \xi_2). \]
It will be noted that (3.4) and (3.5) correspond to (2.10) and (2.8) for \( \Phi = \Gamma \), with
\[ \lambda_\ell = \frac{1}{\ell(\ell+1)}^{-1}. \]

**Proposition 3.1.** Assume \( \Phi \) satisfies C1, C2 and C3. Then: (a) each eigenspace of the associated integral operator is \( G \)-invariant, (b) each kernel \( \Phi_\ell \) satisfies C1, C2 and C3.

**Proof.** (a) follows from the equalities, valid for \( f \) satisfying \( Af = \lambda f \) and \( g \in G \),
\[ A(g \cdot f)(\xi) = \int_{S^2} \Phi(\xi, \eta)f(g^{-1}\eta)d\eta = \int_{S^2} \Phi(g^{-1}\xi, g^{-1}\eta)f(g^{-1}\eta)d\eta \]
\[ = \int_{S^2} \Phi(g^{-1}\xi, g^{-1}\eta)f(g^{-1}\eta)d\eta = \int_{S^2} \Phi(g^{-1}\xi, \eta)f(\eta)d\eta \]
\[ = (Af)(g^{-1}\xi) = \lambda f(g^{-1}\xi) = \lambda(g \cdot f)(\xi) \]
where for the second and third equalities we used the \( G \)-invariance of \( \Phi \) and \( d\eta \) respectively. For (b), C1 follows readily from the fact that for each \( \ell \geq 1 \), \( \Phi_\ell(\xi, \cdot) \) is
the orthogonal projection of $\Phi(\xi,.)$ into $E_\ell$. Next remark that C2 is fulfilled for $\Phi$

means that the constant function $1 : \xi \mapsto 1$ belongs to ker $A$. From (3.3) we obtain

$\Psi (\xi,.) \in E_\ell \subseteq (\ker A)^\perp$ which implies $(\Psi (\xi,.)|1) = 0$ and C2 is satisfied. By

invariance of the inner product under $G$–action it is clear that for each orthonormal

basis $(\phi_m^n)_{m}$ the set $(g\cdot \phi_m^n)_{m}$ is another orthonormal basis of $E_\ell$. The remark made

before (3.4) then allows us to write $\Phi (g \cdot \xi_1, g \cdot \xi_2) = \sum g \cdot \phi_m^n (\xi_1) g \cdot \phi_m^n (\xi_2) = \sum \phi_m^n (\xi_1) \phi_m^n (\xi_2) = \Phi (\xi_1, \xi_2)$ and C3 is satisfied. □

For each $G \in G$, let $\hat{G}$ denote the set of characters corresponding to a complete

set of mutually nonisomorphic irreducible unitary representations of $G$. For each

$\chi \in \hat{G}$, $d_\chi$ denotes the degree of $\chi$. The set $\hat{G}$ is finite whenever $G$ is finite, or

countably infinite otherwise. If $G$ is not finite, let $dg$ be the invariant measure (or

Haar measure) of the group $G$. We are only concerned with real valued statistics

and random variables. We shall therefore consider a set of characters, say $\Upsilon$, such

that

(3.6) $G \in G$, $\Upsilon \subseteq \hat{G}$ and each $\chi \in \Upsilon$ has values in $\mathbb{R}$.

Assertion (a) in Proposition 3.1 enables us to define a linear representation $T_\ell$

of $G$ in $E_\ell$ by putting, for each $g \in G$,

(3.7) $T_\ell (g) : E_\ell \rightarrow E_\ell$

For any function $f : S^2 \rightarrow \mathbb{R}$ and $\chi \in \hat{G}$ we set

(3.8) $P_\chi f (\xi) := \begin{cases} \frac{d_\chi}{|G|} \sum_{g \in G} \chi (g) f(g^{-1}\xi) & \text{if } G \text{ is finite,} \\ \int_G \chi (g) f(g^{-1}\xi) dg & \text{if } G \text{ is not finite.} \end{cases}$

THEOREM 3.1. Assume (3.6) is fulfilled. Let $\Phi$ be a kernel satisfying the four

conditions C1–C4. Let $\chi_\ell$ denote the character of the representation (3.7). For each

$\chi \in \hat{G}$, the mapping $f \in E_\ell \mapsto P_\chi f$ is an orthogonal projection of $E_\ell$ into $E_\chi \subseteq E_\ell$.

If $\chi_1, \chi_2 \in \Upsilon$ and $\chi_1 \neq \chi_2$ then the spaces $E_\chi^{\chi_1}$ and $E_\chi^{\chi_2}$ are orthogonal. The space

$E_\chi^{\chi_1}$ is $G$–invariant and of dimension

$$
\dim E_\chi^{\chi_1} = d_\chi < \chi_1|\chi >, \text{ where } < \chi_1|\chi > := \begin{cases} |G|^{-1} \sum_{g \in G} \chi_1 (g) \chi (g) & \text{if } G \text{ is finite,} \\ \int_G \chi (g) \chi_1 (g) dg & \text{if } G \text{ is not finite.} \end{cases}
$$

If furthermore (3.6) is satisfied with $\Upsilon = \hat{G}$, then

(3.9) $E_\ell = \bigoplus_{\chi \in \hat{G}} E_\chi^{\chi_1}$, hence $(\ker A)^\perp = \bigoplus_{\ell \geq 1} \bigoplus_{\chi \in \hat{G}} E_\chi^{\chi_1}$.

PROOF. This Theorem follows from results proved in [15]. See Theorem 8 p.21 for the case where $G$ is finite. For the case where $G$ is not finite, we use the extensions of the preceding Theorems stated in assertions (a) and (e) in § 4.3. □

We are now equipped to deal with the decomposition our $G$–invariant $U$–statistic.

From a kernel $\Phi$, we obtain a new kernel by setting

(3.10) $\Phi^\chi (\xi,.) := P_\chi \Phi (\xi,.)$.
Proposition 3.2. Assume (3.6) is satisfied. Let $\Phi$ be a kernel fulfilling the four conditions C1-C4. Then for each $\chi \in \Upsilon$ the latter are also satisfied by $\Phi^\chi$, the expansion (3.5) referred to in C4 being replaced for $\Phi^\chi$ by

$$
\Phi^\chi(\xi_1, \xi_2) = \sum_{\ell=1}^\infty \lambda_\ell \Phi^\chi(\xi_1, \xi_2).
$$

For each $\xi_1 \in S^2$, the convergence in (3.11) is pointwise for each $\xi_2 \in S^2$, except maybe for $\xi_2$ belonging to a finite or countable set.

**Proof.** When $G$ satisfies (3.6), we know from [15], assertion (ii) of Proposition 1 p.10 that $\chi(g^{-1}) = \chi(g)$ for each $g \in G$. To avoid notational cumbersome, we restrict the proof concerning the symmetry in C1 to the case where $G$ is finite. We have

$$
P^\chi \Phi(\xi, \eta) = \frac{d_\chi}{|G|} \sum_{g \in G} \chi(g) \Phi(\xi, g^{-1} \eta) \quad \text{by definition of } P^\chi(\Phi)
$$

$$
= \frac{d_\chi}{|G|} \sum_{g \in G} \chi(g) \Phi(\xi, g) \quad \text{by changing } g \text{ into } g^{-1} \text{ and using } \chi(g^{-1}) = \chi(g)
$$

$$
= \frac{d_\chi}{|G|} \sum_{g \in G} \chi(g) \Phi(g^{-1} \xi, \eta) = \frac{d_\chi}{|G|} \sum_{g \in G} \chi(g) \Phi(\eta, g^{-1} \xi) = P^\chi(\Phi(\eta, \xi))
$$

where for the last equalities we used the $G$-invariance and the symmetry of $\Phi$. Thus $\Phi^\chi$ is symmetric. The second assertion in C1 is a direct consequences of the spectral decomposition (3.3) and the fact that the restriction of $P^\chi$ to each $E_\ell$ is an orthogonal projection. C2 follows readily from assertion (b) in Proposition 3.1. For C3 we first notice that (iii) in Proposition 1 p.10 in [15] implies $\chi(h^{-1}g h) = \chi(g)$ for $g, h \in G$. And this enables us to obtain, for any $h \in G$, the relations

$$
P^\chi \Phi(h \xi, h \eta) = \frac{d_\chi}{|G|} \sum_{g \in G} \chi(g) \Phi(h \xi, g^{-1} h \eta) = \frac{d_\chi}{|G|} \sum_{g \in G} \chi(h g h^{-1}) \Phi(h \xi, (h g h^{-1})^{-1} h \eta)
$$

$$
= \frac{d_\chi}{|G|} \sum_{g \in G} \chi(g) \Phi(h \xi, h g^{-1} \eta) = \frac{d_\chi}{|G|} \sum_{g \in G} \chi(g) \Phi(\xi, g^{-1} \eta) = P^\chi(\Phi(\xi, \eta))
$$

which proves C3. We omit details for C4. \qed

The preceding lemma enables us to define new $G$-invariant degenerate $U$-statistics with kernels $\Phi^\chi$ defined by (3.10) and

$$
\Phi^\chi(\xi_1, \xi_2) := \sum_{\chi \in \Upsilon} \Phi^\chi(\xi_1, \xi_2), \quad \Phi^\chi(\xi_1, \xi_2) := \Phi(\xi_1, \xi_2) - \Phi^\chi(\xi_1, \xi_2)
$$

and the corresponding $U$-statistics

$$
U_n^\chi(\xi_1, \ldots, \xi_n) := \frac{2}{(n-1)} \sum_{1 \leq i < j \leq n} \Phi^\chi(\xi_i, \xi_j), \quad (\chi \in \Upsilon)
$$

$$
U_n^\chi(\xi_1, \ldots, \xi_n) := \sum_{\chi \in \Upsilon} U_n^\chi(\xi_1, \ldots, \xi_n),
$$

$$
U_n^\chi(\xi_1, \ldots, \xi_n) := U_n(\xi_1, \ldots, \xi_n) - \sum_{\chi \in \Upsilon} U_n^\chi(\xi_1, \ldots, \xi_n).$$
Theorem 3.2. Assume (3.6) is satisfied and let $\Phi$ be a kernel fulfilling the four conditions C1-C4. Then one has for each $n \geq 2$ and almost every $n$-tuple $\xi_i$, $(1 \leq i \leq n)$,

$$U_n(\xi_1, \ldots, \xi_n) = \sum_{\chi \in \Gamma} U_n(\xi_1, \ldots, \xi_n) + \bar{U}_n(\xi_1, \ldots, \xi_n).$$

Under $H_0$, the statistics $U_n(\chi \in \Upsilon)$ and $\bar{U}_n(\chi \in \Upsilon)$ are asymptotically pairwise independent and one has the convergence in law

$$\lim_{n \to \infty} U_n(\chi \in \Upsilon) = \sum_{\ell \geq 1} \lambda_\ell C_\ell(d\chi < \chi \ell|\chi >), \quad \lim_{n \to \infty} \bar{U}_n(\chi \in \Upsilon) = \sum_{\ell \geq 1} \lambda_\ell C_\ell(d\chi < \chi \ell|\chi >),$$

and

$$\lim_{n \to \infty} \bar{U}_n(\chi \in \Upsilon) = \sum_{\ell \geq 1} \lambda_\ell C_\ell(d\chi < \chi \ell|\chi >)$$

where $\chi_\ell$ is the character of representation (3.7).

Proof. This Theorem is a consequence of Theorem 3.1 combined with basic results from the theory of orthogonal expansions applied to $U-$ statistics, see, e.g., [7], Theorem 4.3.1 p.138.

4. Application to goodness of fit tests with $G-$ invariant hypotheses

We first discuss the consistency of tests based on $U_n$ or the statistics (3.13) – (3.15). Let $F_{S^2} \subseteq L^2(S^2)$ denote the set of probability density functions on the sphere.

Proposition 4.1. Suppose that $F_0, F_1 \subseteq F_{S^2}$ and $f_0 \in F_0$. The test based on rejecting $H_0 : f \in F_0$, against $H_1 : f \in F_1$, for large absolute values of the $U-$ statistic defined by (3.2) is consistent when

$$F_0 \subseteq \ker A, \quad F_1 \cap \ker A = \emptyset,$$

$A$ being the integral operator associated with $\Phi$. In particular the test of uniformity based on $U_{\Gamma, n}$ is consistent against all alternatives.

Proof. If $f \in F_1$ holds, the $U-$ statistic $U_n$ with kernel $\Phi$ is non degenerate, and we know from [7], Theorem 4.2.1, or [14], Theorem A p.192 that there exist $\mu \in \mathbb{R}$ and $\sigma > 0$ such that the convergence in law $n^{1/2}(U_n/n - \mu) \to \mathcal{N}(0, \sigma^2)$ holds. When compared with (2.3), this convergence implies the desired result. In the particular case where $\Gamma = \Phi$ and $F_0 = \{f_0\}$, we use the fact that the kernel of the integral operator associated with $\Gamma$ is the set of constant functions whose orthogonal is generated by the set of nonconstant spherical harmonics.

We now fix $\Phi = \Gamma$. Recall that the trivial representation of a group $G$ denoted by $\chi_0$ is the representation of degree one defined by $\chi_0(g) = 1$ for each $g \in G$. In this case we shall use the notations $\Gamma^G, U^G_{\Gamma, n}, \bar{U}^G_{\Gamma, n}$ and $E^G_\ell$ instead of $\Gamma^{\chi_0}, U^{\chi_0}_n, \bar{U}^{\chi_0}_n$ and $E^{\chi_0}_\ell$. Let $\mathcal{F}_G$ denote the set of $G-$ invariant distributions on the sphere. The cases where $F_0 = \{f_0\}, F_1 = \mathcal{F}_G \setminus \{f_0\}$ and $F_0 = \mathcal{F}_G, F_1 = F_{S^2} \setminus \mathcal{F}_G$ in Proposition 4.1 correspond to the two goodness of fit tests

(4.2)

$$T : \begin{cases} H_0 : f \text{ is uniform}, \\ H_1 : f \text{ is } G- \text{ invariant but not uniform} \end{cases} \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \ Quad
Proposition 4.2. Assume (3.6). A test based on rejecting $H_0$ (resp. $H'_0$) for large values of $|U^G_{Γ,n}|$ (resp. $|U^G_{Γ,n}|$) is consistent against $H_1$ (resp. $H'_1$). One has under $H_0$ the convergence in law

$$U^G_{Γ,n} \rightarrow \sum_{ℓ \geq 1} C_ℓ (\dim E^G_ℓ) \frac{C_ℓ}{ℓ(ℓ+1)} \text{ with } E^G_ℓ = \{ f \in E_ℓ : f \text{ is } G\text{-invariant} \}$$

and under $H'_0$:

$$U^G_{Γ,n} \rightarrow \sum_{ℓ \geq 1} C_ℓ (2ℓ+1 - \dim E^G_ℓ) \frac{C_ℓ}{ℓ(ℓ+1)}$$

Proof. Except for the consistency, the results of this Proposition are a restate-ment of Theorem 3.2 in two particular cases. Concerning the consistency, the fact that (4.1) is fulfilled in both cases is easily seen after noticing that $f \mapsto P^{\sigma_0} f =: f^G$ is an orthogonal projection into $F_G$. This implies the equivalences

$$(f|Γ^G(ξ,.) = 0 \iff (f^G|Γ(ξ, .) = 0,$$

$$(f|Γ(ξ, .) - Γ^G(ξ, .) = 0 \iff (f - f^G|Γ^G(ξ, .) = 0.$$ 

Example 4.1. Assume $G = SO(2)$ is the group of rotations $g$ through an angle $ϕ \in [0, 2π]$ around the polar axis, with Haar measure $dg = dϕ/(2π)$. We obtain

$$Γ^{SO(2)}(ξ, ξ) = \int_0^{2π} Γ(ξ, ξ) \frac{dϕ}{2π} = \frac{1}{4\pi} \log \frac{e (1 - \cos θ_1)(1 + \cos θ_2)}{4}.$$ 

Under $H_0$: $U^{SO(2)}_{Γ,n} \rightarrow \sum_{ℓ=1}^{∞} C(1)_{ℓ(ℓ+1)}$ and under $H'_0$: $U^{SO(2)}_{Γ,n} \rightarrow \sum_{ℓ=1}^{∞} C(2)_{ℓ(ℓ+1)}$.

Example 4.2. Antipodal symmetry is invariance under the action of the group $\{I, σ\}$ where $I$ is the identity and $σ$ the reflection through the origin. The corresponding kernel is

$$Γ^{I,σ}(ξ, ξ) = \frac{Γ(ξ, ξ) + Γ(ξ, σ \cdot ξ)}{2} = -\frac{1}{4\pi} \log \frac{e}{2} (1 - |ξ_1 \cdot ξ_2|^2)$$

Under $H_0$: $U^{I,σ}_{Γ,n} \rightarrow \sum_{ℓ \text{ even}} C(2ℓ+1)_{ℓ(ℓ+1)}$ and under $H'_0$: $U^{I,σ}_{Γ,n} \rightarrow \sum_{ℓ \text{ odd}} C(2ℓ)_{ℓ(ℓ+1)}$.

Example 4.3. The aim of this example is to show how the character table of a finite group can be used in order to write (3.8) explicitly. We follow the notations introduced in [15] §5.8. If $G$ is the symmetry group of a regular tetrahedron it has 24 elements partitioned into 5 equivalence classes denoted 1, $(ab)$, $(ab)(cd)$, $(abc)$ and $(abcd)$. Furthermore we have $\tilde{G} = \{χ_0, ө, θ, ψ, ψε, ψ\}$ and these five characters are real valued. Hence $Γ$ can be decomposed into five components. For example one of them corresponds to $χ = θ$, character of degree $d_θ = θ(1) = 2$. Therefore (3.8) is written, in view of the character table of $G$,

$$Γ^θ(ξ_1, ξ_2) = \frac{2}{24} [2Γ(ξ_1, ξ_2) + \sum_{g ∈ \{ab\}(cd)} 2Γ(ξ_1, gξ_2) - \sum_{g ∈ \{abc\}} Γ(ξ_1, gξ_2)]$$

Remark 4.4. We are now in a position, as claimed in the introduction, to show that Watson’s identity and generalizations given in [9]. Theorem 3 is related to the canonical decomposition of a group representation. These identities correspond to a decomposition of the form (3.16), applied to the covariance function or trajectories of the Gaussian processes appearing in these identities in the following way. Consider a group $G$ acting on a set $S$, on which is defined a Gaussian process
\[ f(x, \omega) = f(x), \ x \in S. \] Assume moreover that the latter has a covariance function \( \Phi \) satisfying the invariance property,

\[ \Phi(x, y) = \Phi(g \cdot x, g \cdot y) \quad \text{whence } \quad f(x) \overset{(\text{in law})}{=} f(g \cdot x) \quad (x \in S, g \in G). \]

We restrict ourselves to the case of Watson’s identity given in [16], relation (7), with a new proof and references for different proofs. In [10] we gave an elementary proof of this identity, based on the decomposition of a function \( f : S = [0, 1] \to \mathbb{R} \):

\[ f(x) = f_1(x) + f_2(x) := \frac{f(x) + f(1-x)}{2} + \frac{f(x) - f(1-x)}{2} \]

The group \( G \) of isometries of \([0, 1]\) is \( \{ \iota, s \} \) with \( \iota(x) = x, \ s(x) = 1-x \). One has \( \hat{G} = \{ \chi_1, \chi_2 \} \) with \( \chi_1(\iota) = \chi_1(s) = 1 \) and \( \chi_2(\iota) = -\chi_2(s) = 1 \) hence \( d_{\chi_1} = d_{\chi_2} = 1 \). In this setting the decomposition \( f = f_1 + f_2 \) becomes \( f = P\chi_1 f + P\chi_2 f \) where the projections are defined by (3.8).
